Real-Time Monitoring of Thermally Induced Trans Fats in Corn Oil Using the FatIR™ Oil Analysis System

INTRODUCTION

Trans fats (TFA) are unsaturated fatty acids whose carbon chains contain double bonds in the trans configuration rather than the more common cis configuration. Edible oils have only negligible amounts of TFA. However, when exposed to heat the cis double bonds in oil may be isomerized to their trans configuration. The amount of thermal isomerization is a function of temperature, exposure time and degree of unsaturation of the oil. In this application we monitored in real-time in situ the thermal isomerization of corn oil at a moderate temperature (102°C).

EXPERIMENTAL CONDITIONS

The spectra of the heated corn oil were collected in situ using the FatIR™ in an infrared spectrometer with a DTGS detector and conditions set for 32 scans at 4 cm⁻¹ resolution. Corn oil was placed on the slightly preheated (30°C) crystal covering the entire sampling surface. The spectrum of corn oil at 30°C was collected. The temperature of the crystal was slowly raised from 30°C to 102°C over a 15 minute period. Spectra of the corn oil at 102°C were collected after 0, 5, 30, 70, 115 and 155 minutes. The crystal was allowed to cool to 30°C and the spectrum of the cooled corn oil was collected. The spectrum of corn oil at 102°C recorded at t = 0 minutes was subtracted from the spectra recorded after t = 5, 30, 70, 115 and 155 minutes.

RESULTS

Figure 2 illustrates the changes that take place in the trans double bond region (1050-900 cm⁻¹) of the spectrum due to prolonged exposure to moderate heat. There is a marked progressive rise in the 966 cm⁻¹ peak with time. In addition to the rise of the 966 cm⁻¹ peak there is also an initial increase in the 985 cm⁻¹ peak that disappears later on.

The increase of the trans band with time is paralleled with a decrease of the band at 3010 cm⁻¹ associated with the CH stretching vibration of cis double bonds (Figure 3). By comparing the spectra of corn oil before heating (T = 30°C) and after cooling back to 30°C, in the regions of interest (Figures 4 and 5), we see that there are heat induced changes in the trans and cis regions. Specifically, there is an increase in the concentration of the trans isomers and...

Figure 5. Real-time spectra in the cis bond region of corn oil at 30°C before heating (blue), after cooling (red).

CONCLUSION

The new FDA requirement that trans fats be included in the Nutrition Facts panel has created a need for the routine determination of the total trans fat content of edible oils and fats and for the monitoring of the formation of trans isomers during processing of vegetable oils.

Harrick Scientific’s FatIR™ Oil Analysis System not only provides a fast and easy way for the routine determination of the total trans fat content in edible oils and fats, but also enables real-time in situ monitoring of the formation of heat induced TFA.
